Consider the experiment of throwing a die. If a multiple of 3 comes up, throw the die again. If any other number comes up, toss a coin. Find the conditional probability of the event the coin shows a tail, given that at least one die shows a 3.
Solution: Let, the states S_0 and S_1 describe the outcomes of dice throws.
S_2 and S_3 describe the outcomes of coin toss.

$$S_0 = \Sigma(Y = k); k \in (3, 6) \tag{1}$$
$$S_1 = \Sigma(Y = k); k \in (1, 2, 4, 5) \tag{2}$$
$$S_2 = \text{Outcome of coin toss is heads} \tag{3}$$
$$S_3 = \text{Outcome of coin toss is tails} \tag{4}$$

Conditional Probability is that "The coin shows tails" given that "at least one die shows a 3". Since, a Markov chain does not depend on the past outcomes,

$$P_{(S_3|S_0)} = P_r(X_n = S_3 | X_1 = S_0) \tag{5}$$

Transition Probability Matrix is given as,

$$P = \begin{pmatrix} \frac{1}{3} & \frac{2}{3} & 0 & 0 \\ 0 & 0 & \frac{1}{2} & \frac{1}{2} \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \tag{6}$$

And State vector is ,

$$Q_0 = \begin{pmatrix} 1 & 0 & 0 & 0 \end{pmatrix} \tag{7}$$

Since the chain starts form S_0 according to Markov chain. The long term Probability that system will be in each state is called stationary state, and stationary state probability is given as,

$$A\pi = \pi \tag{8}$$

where π is steady state probability vector.
So,after long time,

$$Q_1 = Q_0 P \tag{9}$$
$$Q_2 = Q_1 P \tag{10}$$
$$\vdots \tag{11}$$
$$Q_n = Q_{n-1} P \tag{12}$$

So substituting the state vectors we get,

$$Q_n = Q_0 P^n \tag{13}$$
$$\tag{14}$$

applying limits to find the stationary probability vector,

$$\lim_{n \to \infty} Q_n = Q_0 P^n \tag{15}$$

By substituting the values of Q_0 and P in the above equation, We get the steady state probability vector as,

$$\pi = \begin{pmatrix} 0 & 0 & \frac{1}{2} & \frac{1}{2} \end{pmatrix} \tag{16}$$

So, the probability that "coin shows tails" given that "Die shows at least one 3" is,

$$p_{(3|1)} = \frac{1}{2} \tag{17}$$
